

# Diabetes

## Teaching Plan

This lesson is designed to help assisted living workers learn about diabetes. To use this lesson for self-study, the learner should read the materials, do the case study activity, and take the test. For group study, the leader should give every learner a copy of the learning guide and use the suggested group activities to teach the lesson. *Approximate lesson time: One hour.*

### Learning Objectives

Participants in this activity will be able to:

1. Explain what diabetes is and does.
2. Describe the four key elements of treatment for diabetes.
3. List the symptoms of low blood sugar and high blood sugar.
4. Know how to respond to a diabetic emergency.

### Teaching Tip

When lecturing, move around the room a little to provide visual interest. Focus attention by writing main points on a board.

## Suggested Group Activities

### Introductory Activity:

Give the learners a copy of the case study activity. Ask them to read the case studies and think about their responses. Explain that they will learn answers to these problems today.

### What Diabetes Is and Does:

Go over the material in the learner guide about what diabetes is, the two types of diabetes, and the long-term effects of diabetes. You can do this as a mini-lecture. Point out that the pancreas is located behind the stomach, in front of the lower part of the backbone.

### The Four Key Elements of Treatment:

Review and discuss the material together, asking learners to read portions of the lesson aloud to the others. Emphasize the points that are of particular concern in your facility.

### Diabetic Emergencies:

Ask the workers to study the symptoms of low blood sugar and high blood sugar for a minute. Quiz them by calling out a symptom and asking if it means high blood sugar or low blood sugar. For fun, throw a small piece of candy to the first person to call out the correct answer. Observe that some similar symptoms occur in both conditions, but low blood sugar happens suddenly. High blood sugar symptoms usually appear gradually and become worse.

Ask the learners to tell you how to respond to each type of diabetic emergency. Be sure they know that low blood sugar can cause heart attacks and strokes if not treated promptly.

### Conclusion:

Review the case studies again with the group, asking what should be done in these situations. See if their responses have changed since learning this material. Guide them to understand the correct procedures to follow in your facility, using the answer sheet to assist you.

Have the learners take the test, then grade the test together. Hand out certificates.

# Diabetes

## Learning Guide

**D***iabetes* is a disease that changes the way our bodies use food. It causes the level of sugar in the blood to be too high. The extra sugar harms the blood vessels and other organs in the body over time. Diabetes can cause great damage before any symptoms appear.

When we eat, our bodies digest the food and turn it into sugar, or *glucose*. In a normal healthy person, an organ called the *pancreas* produces *insulin*, a hormone. Insulin helps the body's cells use glucose to produce energy. The cells use this energy to keep our bodies healthy.

In someone with diabetes, either the pancreas is not producing enough insulin or the body does not use its insulin effectively. The cells cannot turn sugar into energy, and the sugar builds up in the blood. The cells are starved for energy, and the blood carries dangerously high levels of sugar that can't be used.

### There Are Two Main Types of Diabetes:

*Type I* means that the pancreas is not producing insulin, or is producing very little. This type always requires shots of insulin injected into the body every day.

*Type II* means that the pancreas is producing insulin, but not enough, or that the body does not use its insulin effectively.

Nine out of ten cases of diabetes are Type II. It usually occurs in people over age 45 who are overweight. It can be treated by diet, exercise, and/or medications that are taken by mouth. Sometimes it also requires insulin injections.

### Why Is It Important to Control Diabetes?

The goal of treatment for diabetes is to keep the individual's blood sugar as close to normal as possible for that person. Doing this will lower the person's chances of getting:

- Stroke
- Heart disease
- Kidney failure
- Stomach disease
- High blood pressure
- Eye disease, loss of vision, or blindness
- Nerve damage, with pain or loss of feeling in hands, feet, legs, or other parts of the body

A high level of sugar in the blood over a long period of time causes these problems.

### There are Four Parts to Diabetic Treatment:

1. Diet
2. Exercise
3. Medicine
4. Monitoring

We will discuss each of these elements of treatment. Anyone who helps a diabetic person should be familiar with the medicine, exercise regimen, monitoring program, and diet that the individual is supposed to follow.

## 1. Diet

There is no one diabetic diet designed for every diabetic person. There are guidelines to help diabetics with food choices. These guidelines are very similar to the kind of eating that is healthy for anyone. These are the main rules that should be followed:

1. Eat few sugary foods.
2. Eat less fat, especially saturated fat and cholesterol (butter, margarine, oils).
3. Eat a variety of fresh fruits, vegetables, lean meats, & fish.
4. Eat just enough calories to stay at a healthy weight.

### The Diabetes Food Pyramid

Diabetics should eat the recommended number of servings from all the food groups on this pyramid every day, except for the fats, sweets, and alcohol. No one needs sweets or alcohol for good nutrition (they can be an occasional treat), and we get plenty of fats from the other food groups. The exact number of servings a diabetic should have from each group depends on individual calorie and nutrition needs, weight goals, exercise level, and preferences.

Many people think that diabetics are not allowed to eat sugar of any kind. This is no longer required. Sugar is a carbohydrate, like bread or potatoes, and can be part of the diabetic's food plan. However, most sugary foods provide calories without many vitamins or minerals, and they are often high in fat. It is better to eat more foods rich in nutrients, like vegetables and fruits, and very few fatty, sweet foods like ice cream and candy.

Dieticians sometimes teach diabetics and those who care for them to use Exchange Lists. These lists are a way to plan meals by putting foods in a category, such as a starch exchange or fruit exchange. Foods on a list can be substituted for each other and sometimes for foods on other exchange lists. The diabetic person eats only a certain number of each type of exchange every day, as ordered by a doctor or established by the dietician.

## 2. Exercise

Exercise usually lowers blood sugar and may help insulin work better. It helps control weight, it improves blood flow, and it strengthens the heart. People with diabetes should exercise at least three times a week. Before a diabetic starts a new exercise program, a doctor should approve what kind, how often, and how long the diabetic exercises. Elderly and disabled people need to exercise also, and should be helped to find an exercise they can do.

It is important that a diabetic not develop low blood sugar while exercising. Since the body burns sugar during exercise, the diabetic should “fuel up” with a piece of fruit or half a sandwich within an hour before starting any exercise. It is also a good idea for the diabetic to check his blood sugar level before he starts exercising. If the blood sugar reading is less than 70, he should eat something and wait for the blood sugar level to come up over 70 before exercising.

If a diabetic feels faint, sweaty, dizzy, or confused while doing any activity, he should stop what he is doing and immediately drink fruit juice or a sweet (not diet) soft drink. He must respond quickly to this feeling, because it means his blood sugar level is too low.

## 3. Medication

Diabetics might receive insulin shots or they may take pills by mouth. Only a doctor can decide what medication and how much of it a diabetic should receive. It can be VERY dangerous to change a diabetic’s medication in any way unless it is ordered by a doctor. Diabetics must receive the exact amount of medicine their doctor has ordered, at the times the doctor has ordered. Timing of medicine and meals is important to prevent low blood sugar.

## 4. Monitoring

Close monitoring of a diabetic’s blood sugar level is one of the best ways for him or her to prevent long-term complications from the disease. Diabetics check their blood sugar by pricking a finger with a needle and testing a drop of blood with a special blood glucose meter. The meter, also called a monitor, gives a number that tells the level of glucose in the blood. These monitors must be kept clean and should be checked for accuracy periodically.

Most diabetics need their blood sugar level tested at least once a day, usually in the morning before breakfast. Depending on the type of diabetes, the age of the person, and other factors, the individual may need his blood glucose tested as much as five times a day. Sometimes insulin dosages are adjusted depending on the blood sugar level. This chart from the National Diabetes Education Program shows the recommended blood sugar levels at different times of the day:

Before Meals	80-130
At Bedtime	100-150

A doctor must set the acceptable ranges for each person, and they might differ from the normal ranges given in the chart. When a blood glucose level falls outside the range set by the doctor, the doctor must be notified as soon as possible. If you are assisting a diabetic with monitoring his blood sugar, be sure you know the correct range for him.

Another important part of monitoring is watching the feet and skin of a diabetic. Diabetes can turn a small sore or wound into a very large problem. Sores, blisters, and wounds on a resident’s feet and skin must always be reported to your supervisor or a nurse.

## DIABETIC EMERGENCIES AND HOW TO RESPOND

Diabetes can cause both long-term and short-term problems. Blood sugar that is too low or extremely high can lead rapidly to unconsciousness and even death. You must know the symptoms of both conditions and know how to respond.

**H**ypoglycemia means that the level of sugar in the blood is too low (less than 70). Too much insulin or oral medication, too much exercise, not eating enough food, or drinking alcohol can cause it. Hypoglycemia can cause strokes and heart attacks in the elderly. This problem is also called *insulin reaction* or *insulin shock*.

Symptoms of Low Blood Sugar--These symptoms occur suddenly and without warning:

- Shaky, nervous
- Sweaty and cold
- Pale, clammy skin
- Weak and tired, drowsy
- Sudden hunger
- Blurred or double vision
- Tingling of hands, lips or tongue
- Confusion
- Personality change
- Slurred speech
- Loss of consciousness
- Dizziness, or a staggering walk
- Nausea
- Headache
- Fast heartbeat
- Itching

Note: Elderly people and people with other diseases and disabilities can be especially sensitive to low blood sugar, and it can be very dangerous for them. Some people may have a reaction even when their blood sugar is not below 70. Any diabetic suddenly showing any of the signs listed above must receive immediate attention.

Treatment:

- The person should drink a sweet drink such as sweetened coffee or tea, orange juice, or soda.
- Or, the diabetic could eat sugar, corn syrup, or candy, or take glucose tablets.

**H**yperglycemia means that the level of sugar in the blood is too high (above 180). It can be caused by infections, illness, stress, injury, not enough insulin, not enough exercise, or eating too much food. Very high levels of sugar can cause coma and death.

Symptoms of High Blood Sugar--These symptoms occur gradually and get worse over time:

- Extreme thirst and/or hunger
- Rapid weight loss
- Frequent urination
- Vision changes
- Dry skin and mouth
- Fatigue, drowsiness
- Nausea
- Fruity-smelling breath
- Very deep, gasping breathing
- Unconsciousness

Treatment:

The first seven symptoms in this list should be reported to your supervisor or a nurse as soon as possible. Fruity-smelling breath, deep gasping breathing and unconsciousness are emergency symptoms that can lead quickly to death. Call 911 or access emergency medical care at once.
